1 Representation of Integers

1.1 Euclidean division

If $a, b \in \mathbb{Z}$ with $b \neq 0$ then $\exists! q, r \in \mathbb{Z}$ such that $a = qb + r$ where $0 \leq r < |b|$. This is the *Euclidean division* or *long division* of the *dividend* a with the *divisor* b . The results of the division are the *quotient* q and the *remainder* r . The standard notation for the remainder is $a \bmod b$. In algorithmic setting we use $q, r \leftarrow \mathbf{divmod}(a, b)$.

1.2 Number systems

Let $1 < b \in \mathbb{Z}$ be the *base* of the *number system*. For each $0 \leq n \in \mathbb{Z}$ there exists a unique $1 \leq d \in \mathbb{Z}$ and a unique set of *digits* $0 \leq n_1, n_2, \dots, n_{d-1} < b$ all integers, such that

$$n = \sum_{k=0}^{d-1} n_k b^k.$$

If $n = 0$, then $d = 1$ and $n_0 = 0$. Otherwise $d = \lfloor \log_b n \rfloor + 1$ and we can extract the digits of n with long division, since

$$\begin{aligned} n &= n_{d-1}b^{d-1} + \dots + n_2b^2 + n_1b + n_0 \\ &= (n_{d-1}b^{d-2} + \dots + n_2b + n_1)b + n_0 \end{aligned}$$

where the quotient $n_{d-1}b^{d-2} + \dots + n_2b + n_1$ is a $d - 1$ digit number and n_0 is the extracted digit.

We call n_0 the *least significant digit* and n_{d-1} the *most significant digit*. The storage order of digits is called *little endian* if we start at the least significant digits and move towards the most significant one. Otherwise it is called *big endian*.

1.3 Operations on Integers

1.3.1 Addition

Let us assume that we have two unsigned integers stored as digits in a number system with base b :

$$n^{(i)} = \sum_{k=0}^{d^{(i)}-1} n_k^{(i)} b^k,$$

for $i = 1, 2$. The following algorithm computes the digits of the sum $s = n^{(1)} + n^{(2)} = \sum_{k=0}^{d^{(s)}-1} s_k b^k$:

Algorithm 1 Standard addition

```

1: procedure STANDARDADDITION( $n^{(1)}, n^{(2)}$ )
2:    $d^{(s)} \leftarrow \max(d^{(1)}, d^{(2)})$ 
3:    $c \leftarrow 0$ 
4:   for  $k = 0, \dots, d^{(s)} - 1$  do
5:      $c, s_k \leftarrow \text{divmod}(n_k^{(1)} + n_k^{(2)} + c, b)$ 
6:   end for
7:   return  $s$ 
8: end procedure

```

In Algorithm 1 we assume that $n_k^{(i)} = 0$ if $k \geq d^{(i)}$ for $i = 1, 2$. The time complexity of the standard addition is $O(d^{(s)})$.

1.3.2 Multiplication

Let $n^{(i)}$'s defined same as above for $i = 1, 2$. We will compute the digits of the product $p = n^{(1)} \cdot n^{(2)} = \sum_{k=0}^{d^{(p)}-1} p_k b^k$ with the naive multiplication method:

The time-complexity of Algorithm 2 is $O(d^{(1)} \cdot d^{(2)}) = O(d^2)$, where $d = \max(d^{(1)}, d^{(2)})$.

Karatsuba's idea for faster multiplication can be demonstrated on two-digit numbers. Let

$$x = x_1 b + x_0, \text{ and } y = y_1 b + y_0$$

with $0 \leq x_i, y_i < b$ integers. Naive multiplication of x and y is

$$\begin{aligned}
z = xy &= (x_1 b + x_0)(y_1 b + y_0) \\
&= x_1 y_1 b^2 + (x_1 y_0 + x_0 y_1) b + x_0 y_0 \\
&= z_1 b^2 + z_1 b + z_0.
\end{aligned}$$

This is 4 multiplication and 1 addition.

Algorithm 2 Naive multiplication

```
1: procedure NAIVEMULTIPLICATION( $n^{(1)}, n^{(2)}$ )
2:    $d^{(p)} \leftarrow d^{(1)} + d^{(2)}$ 
3:   for  $k = 0, \dots, d^{(p)} - 1$  do
4:      $p_k \leftarrow 0$ 
5:   end for
6:   for  $j = 0, \dots, d^{(2)} - 1$  do
7:      $c \leftarrow 0$ 
8:     for  $i = 0, \dots, d^{(1)} - 1$  do
9:        $c, p_{i+j} \leftarrow \text{divmod} \left( p_{i+j} + n_i^{(1)} n_j^{(2)} + c, b \right)$ 
10:    end for
11:     $p_{d^{(1)}+j} \leftarrow c$ 
12:  end for
13:  return  $p$ 
14: end procedure
```

Now we can express

$$\begin{aligned} z_1 &= x_1 y_0 + x_0 y_1 \\ &= x_1 y_0 + x_0 y_1 - x_1 y_1 + x_1 y_1 - x_0 y_0 + x_0 y_0 \\ &= (x_1 + x_0) y_1 + (x_1 + x_0) y_0 - x_1 y_1 - x_0 y_0 \\ &= (x_1 + x_0) (y_1 + y_0) - x_1 y_1 - x_0 y_0 \\ &= (x_1 + x_0) (y_1 + y_0) - z_2 - z_0. \end{aligned}$$

This is 3 multiplication and 3 additions. By extending this idea to more than two digits recursively, the multiplication algorithm performs $O(d^{\log_2 3}) \approx O(d^{1.58})$ single-digit multiplication.

Fast Fourier Transform based algorithms can achieve $O(d \log d)$ complexity.

1.4 Exponentiation

We want to compute x^n for some $1 \leq n \in \mathbb{Z}$ and x that has multiplication as an operation.

Naive exponentiation By repeated multiplication, we can compute

$$x^n = \underbrace{x \cdot x \cdots x}_{n \text{ times}}.$$

This method requires $n - 1$ multiplications.

Repeated squaring If $n = 2^s$ for $0 < s \in \mathbb{Z}$, then

$$x^{(2^s)} = (x^2)^{(2^{s-1})}.$$

This way we can compute x^n with $\log_2 n = s$ multiplications with the algorithm below:

Algorithm 3 Repeated squaring

```

1: procedure REPEATEDSQUARING( $x, s$ )
2:    $y \leftarrow x$ 
3:   for  $k = 0, \dots, s - 1$  do
4:      $y \leftarrow y^2$ 
5:   end for
6:   return  $y$ 
7: end procedure

```

Fast exponentiation If we write $n = \sum_{k=0}^{d-1} n_k 2^k$ in binary, then

$$\begin{aligned}
 x^n &= x^{(\sum_{k=0}^{d-1} n_k 2^k)} \\
 &= \prod_{k=0}^{d-1} x^{(n_k 2^k)} \\
 &= \prod_{k=0}^{d-1} x^{(2^k)^{n_k}}.
 \end{aligned}$$

Since $y^{n_k} = y$ if $n_k = 1$ and $y = 1$ otherwise, we arrive at the following algorithm:

Algorithm 4 Fast exponentiation

```

1: procedure FASTEXP( $x, n$ )
2:    $y \leftarrow 1$ 
3:   while  $n > 0$  do
4:      $n, r \leftarrow \text{divmod}(n, 2)$ 
5:     if  $r = 1$  then
6:        $y \leftarrow y \cdot x$ 
7:     end if
8:      $x \leftarrow x^2$ 
9:   end while
10:  return  $y$ 
11: end procedure

```

This algorithm requires $O(\log_2 n)$ multiplication.

2 Number Theory and its Applications

2.1 Divisibility

If $aq = b$, then we say that a is a *divisor* of b , or b is a *multiple* of a . The notation is $a \mid b$. Otherwise $a \nmid b$. If $a \mid b$, then long division has remainder of 0 and in case of integers $\frac{b}{a}$ is an integer as well.

The following properties are natural consequences of the definition.

1. For every a , we have that $a \mid a$.
2. $a \mid 0$, for every a .
3. If $0 \mid a$, then $a = 0$.
4. If $a \mid b$ and $b \mid c$, then $a \mid c$.
5. If $a \mid b$ and $c \mid d$, then $ac \mid bd$.
6. If $a \mid b$, then $ac \mid bc$ for every c .
7. If $ac \mid bc$ and $c \neq 0$, then $a \mid b$.
8. If $a \mid b_i$ for some finite indices i , then $a \mid \sum_i c_i b_i$ for every c_i .

If $\varepsilon \mid a$ for every a , then we call ε a *unit element*. The unit elements of \mathbb{Z} are ± 1 .

If $a \mid b$ and $b \mid a$ and $a \neq b$, then we call a and b *associated elements*. Two elements a and b are associated if and only if $a = \varepsilon b$ for some unit element ε . Consequently, a and b are associated integers if and only if $|a| = |b|$.

Let $p \neq 0$ be a non-unit element. We say that p is an *irreducible element* if $p = ab$ implies that a or b is an associated element of p (and the other is a unit). If an element is not irreducible, then it is *composite*. We call p a *prime element* if $p \mid ab$ implies that $p \mid a$ or $p \mid b$. If p is an irreducible element, then it is also a prime element. In case of integers, the reverse is also true, i.e. every prime element is irreducible.

Theorem 1 (The Fundamental Theorem of Arithmetic). *If $a \neq 0$ is not a unit element, then it is a product of irreducible elements. The product is unique (up to ordering and up to multiplication with unit elements).*

If $1 < n \in \mathbb{Z}$, then the *canonical form* of

$$n = p_1^{\alpha_1} \cdots p_r^{\alpha_r}$$

where p_i 's are different prime numbers (positive prime elements of \mathbb{Z}) and $\alpha_i > 0$ for all $i = 1, \dots, r$.

Theorem 2 (Euclid). *There are infinitely many prime numbers.*

Proof. Let us assume that there are only finite many primes p_1, \dots, p_n . In this case the long division of $n = p_1 \cdots p_n + 1$ with p_i yields a remainder of 1 for every prime. This means that n does not have canonical form, which contradicts Theorem 1. \square

Theorem 3 (Distribution of prime numbers). *The following statements illustrate some properties of the distribution of prime numbers:*

1. *If $N > 1$, then $\exists a > 2$ such that $a + 1, a + 2, \dots, a + N$ are all composite numbers.*
2. *For every $M > 2$, there is a prime number between M and $2M$.*

Let $\pi(x)$ denote the number of positive prime numbers below x .

Theorem 4 (Prime Number Theorem). *An approximation of $\pi(x)$ is $\frac{x}{\ln x}$. In other words*

$$\lim_{x \rightarrow +\infty} \frac{\pi(x)}{x/\ln x} = 1.$$

2.2 Greatest common divisor

The *greatest common divisor* of a_1, \dots, a_n elements is d , if

- $d \mid a_i$ for all i , i.e. d is a common divisor of the elements and
- if $d' \mid a_i$ for all i , then $d' \mid d$ that is d is maximal with respect to divisibility.

From the definition, it is clear that if d is a greatest common divisor and ε is a unit element, then εd is also a greatest common divisor. We usually fix a greatest common divisor for integers by nominating the positive one. We will use the notation $\gcd(a_1, \dots, a_n)$.

From the definition we can see that

1. $\gcd(a, 0) = a$,
2. $\gcd(0, 0) = 0$,
3. $\gcd(a, b) = \gcd(b, a)$,
4. $\gcd(a, b) = \gcd(a - b, b)$ or in general $\gcd(a - qb, b) = \gcd(a, b)$ for any q . Specifically $\gcd(a \bmod b, b) = \gcd(a, b)$.

From the last property we have that

$$\begin{aligned} \gcd(a, b) &= \gcd(a \bmod b, b) \\ &= \gcd(a \bmod b, b \bmod (a \bmod b)) \\ &= \gcd((a \bmod b) \bmod b \bmod (a \bmod b), b \bmod (a \bmod b)). \end{aligned}$$

Let us define the recurrence relation $r_0 = a$, $r_1 = b$ and $r_{n+2} = r_n \bmod r_{n+1}$. In this case the equations above become

$$\begin{aligned}\gcd(r_0, r_1) &= \gcd(r_2, r_1) \\ &= \gcd(r_2, r_3) \\ &= \gcd(r_4, r_3).\end{aligned}$$

We can swap the arguments of gcd, so

$$\begin{aligned}\gcd(r_0, r_1) &= \gcd(r_1, r_2) \\ &= \gcd(r_2, r_3) \\ &= \gcd(r_3, r_4)\end{aligned}$$

The sequence is strictly decreasing, that is $r_n > r_{n+1}$ and $r_n \geq 0$ from $n = 2$. This means that there is an index N such that $r_N = 0$, but $r_{N-1} > 0$. From the properties and definition of recurrence relation it is clear, that

$$\gcd(a, b) = \gcd(r_{N-1}, 0) = r_{N-1}.$$

The argument above gives the *Euclidean algorithm* in recursive form:

Algorithm 5 Recursive Euclidean algorithm

```

1: procedure GCD( $a, b$ )
2:   if  $b = 0$  then
3:     return  $a$ 
4:   end if
5:   return GCD( $b, a \bmod b$ )
6: end procedure
```

We can transform the recursion into a loop. At any given step, we only need r_n and r_{n+1} to produce r_{n+2} .

Algorithm 6 Iterative Euclidean algorithm

```

1: procedure GCD( $a, b$ )
2:    $r_{\text{old}}, r_{\text{new}} \leftarrow a, b$ 
3:   while  $r_{\text{new}} \neq 0$  do
4:      $r_{\text{old}}, r_{\text{new}} \leftarrow r_{\text{new}}, r_{\text{old}} \bmod r_{\text{new}}$ 
5:   end while
6:   return  $r_{\text{old}}$ 
7: end procedure
```

For later applications we not only need the $\gcd(a, b) = d$ but two additional elements x and y , such that

$$d = ax + by.$$

We can extend Euclidean algorithm to calculate x and y . For this, we are going to ensure that during the algorithm we are updating producing x_n and y_n for each r_n , such that

$$r_n = ax_n + by_n.$$

This will be our loop invariant property, i.e. this property will be true for n and $n + 1$ whenever we enter the body of the loop and we will make sure that it is true for $n + 2$ after the last statement of the body. Before the first execution of the loop body, the values $x_0 = 1$, $y_0 = 0$, $x_1 = 0$ and $y_1 = 1$ will suffice. Let $q = \lfloor r_n / r_{n+1} \rfloor$. During the body of the loop we have that

$$\begin{aligned} r_{n+2} &= r_n \bmod r_{n+1} \\ &= r_n - qr_{n+1} \\ &= (ax_n + by_n) - q(ax_{n+1} + by_{n+1}) \\ &= a(x_n - qx_{n+1}) + b(y_n - qy_{n+1}), \end{aligned}$$

so $x_{n+2} = x_n - qx_{n+1}$ and $y_{n+2} = y_n - qy_{n+1}$ will work. Again, we only need the last two values of x and y during the calculations. We call the procedure *Extended Euclidean algorithm*:

Algorithm 7 Extended Euclidean algorithm

```

1: procedure GCD( $a, b$ )
2:    $r_{\text{old}}, x_{\text{old}}, y_{\text{old}} \leftarrow a, 1, 0$ 
3:    $r_{\text{new}}, x_{\text{new}}, y_{\text{new}} \leftarrow b, 0, 1$ 
4:   while  $r_{\text{new}} \neq 0$  do
5:      $r_{\text{old}}, q, r_{\text{new}} \leftarrow r_{\text{new}}, \text{divmod}(r_{\text{old}}, r_{\text{new}})$ 
6:      $x_{\text{old}}, x_{\text{new}} \leftarrow x_{\text{new}}, x_{\text{old}} - qx_{\text{new}}$ 
7:      $y_{\text{old}}, y_{\text{new}} \leftarrow y_{\text{new}}, y_{\text{old}} - qy_{\text{new}}$ 
8:   end while
9:   return  $r_{\text{old}}, x_{\text{old}}, y_{\text{old}}$ 
10: end procedure

```

2.3 Linear Diophantine equation

Let $a, b, c \in \mathbb{Z}$ and we search for the integers solutions $x, y \in \mathbb{Z}$ for the equation

$$ax + by = c.$$

If $d = \gcd(a, b)$ then $d \mid ax + by$ there $d \mid c$. Otherwise there is no solution. With Extended Euclidean algorithm, we can compute $d = ax' + by'$. Since $d \mid c$, there exists $m \in \mathbb{Z}$ for which $c = d \cdot m$. In summary

$$a(x'm) + (y'm) = d \cdot m = c,$$

so $x_0 = x'm$ and $y_0 = y'm$ is a pair of solution.

If there is a pair of solution, then there are infinitely many solutions in the form of

$$x = x_0 + k \frac{b}{d}, \quad y = y_0 - k \frac{a}{d}$$

where $k \in \mathbb{Z}$ and there are no other solutions.

2.4 Modular arithmetic

Let $m > 1$. We say that a is *congruent to* $b \pmod{m}$, if $m \mid a - b$. The notation for this relation $a \equiv b \pmod{m}$. Otherwise we say, that a is *incongruent to* b , or $a \not\equiv b \pmod{m}$.

For a fixed $m > 1$, $a \equiv b \pmod{m}$ defines an equivalence relation over the \mathbb{Z} . The equivalence classes are called *residue classes*. The residue class of a is

$$\bar{a} = \{a + km : k \in \mathbb{Z}\}.$$

Let us denote

$$\mathbb{Z}_m = \{\bar{0}, \bar{1}, \dots, \overline{m-1}\}$$

the set of residue classes.

Theorem 5 (The compability of integer operations with the residue classes). *If $a \equiv b \pmod{m}$ and $c \equiv d \pmod{m}$, then*

- $a + c \equiv b + d \pmod{m}$ and
- $ac \equiv bd \pmod{m}$.

This can be stated on residue class level as well:

1. $\bar{a} + \bar{b} = \{a' + b' : a' \in \bar{a}, b' \in \bar{b}\} = \overline{a + b}$ and
2. $\bar{a} \cdot \bar{b} = \{a'b' : a' \in \bar{a}, b' \in \bar{b}\} = \overline{ab}$.

Theorem 5 enables us to work on the *residue system* level, i.e. on

$$\mathbb{Z}_m = \{\bar{0}, \bar{1}, \dots, \overline{m-1}\} \simeq \{0, 1, \dots, m-1\}$$

The operations on the residue system can be defined as

$$a +_m b = (a + b) \bmod m, \quad a \cdot_m b = ab \bmod m.$$

Theorem 6 (Structure of \mathbb{Z}_m). *Let $m > 1$ and $a \neq 0$.*

1. *If $\gcd(a, m) \neq 1$, then $ax \equiv 0 \pmod{m}$ has non-zero solution.*
2. *If $\gcd(a, m) = 1$, then $ax \equiv 1 \pmod{m}$ has a solution.*

Proof. 1. If $d = \gcd(a, m) > 1$, then

$$\frac{a}{d}m = a \frac{m}{d} \equiv 0 \pmod{m},$$

so $x = m/d$ is nonzero solution.

2. With the extended Euclidean algorithm, we can compute $1 = ax + my$. Rearranging this, we have that $ax - 1 = -ym$. So $m \mid ax - 1$, which is by definition means that $ax \equiv 1 \pmod{m}$. \square

If $ax \equiv 1 \pmod{m}$, then we call x the *modular inverse* of a , denoted by $a^{-1} \pmod{m}$.

2.5 Solving linear congruence equations

We search for the integer solutions of $ax \equiv b \pmod{m}$. We can convert this expression into the linear Diophantine equation $ax + my = b$. We know that $d = \gcd(a, m) \mid b$, that is $b = s \cdot d$ otherwise there is no solution.

A particular x_0 can be found by extended Euclidean algorithm. If $d = ax' + my'$, then $x_0 = x's$ and the general solutions have the form of $x = x_0 + k\frac{m}{d}$ for integers k .

We know that $x \equiv x + m \pmod{m}$ and for every $1 < n < m$, $x \not\equiv x + n \pmod{m}$. This means if $1 < k\frac{m}{d} < m$, then $x \not\equiv x + k\frac{m}{d} \pmod{m}$. So we can list all the different solutions \pmod{m} with $k = 0, \dots, d - 1$.

2.6 Solving systems of linear congruence relations

No we are searching for common integer solution of the following two linear congruence equations

$$z \equiv a \pmod{c}, \quad z \equiv b \pmod{d},$$

where $a, b \in \mathbb{Z}$ and $0 < c, d \in \mathbb{Z}$.

Theorem 7 (Chinese Remainder Theorem (CRT)). *If $\gcd(c, d) = 1$, then the system above has a solution and the solution is unique \pmod{cd} .*

Proof. We only prove the existence.

With extended Euclidean algorithm we can compute $cx + dy = 1$. If we let $z = bcx + ady$, then

$$bcx + ady \equiv 0 + ady \equiv ady \equiv a \pmod{c},$$

since $c \mid bcx$ and $y = d^{-1} \pmod{c}$. The other congruence relation can proven in the same way. \square

We can extend this method for solving more than two equations by replacing two of them with the common solution calculated with the help of previous theorem.

2.7 Euler's totient function

For $0 < n \in \mathbb{Z}$ we can define *Euler's totient function* as

$$\varphi(n) = |\{a \in \mathbb{Z} : 1 \leq a \leq n, \gcd(a, n) = 1\}|.$$

If p is a positive prime number, then $\varphi(p) = p - 1$.

If $1 < k \in \mathbb{Z}$, then $\gcd(a, p^k) > 1$ means that $p \mid a$ for integers $1 \leq a \leq p^k$. This means that $a = p, 2p, \dots, p^{k-1}p$. Due to this reasoning, we have that

$$\varphi(p^k) = p^k - p^{k-1} = p^k \left(1 - \frac{1}{p}\right).$$

If $\gcd(n, m) = 1$, then $\varphi(nm) = \varphi(n)\varphi(m)$. This last statement is the consequence of CRT.

In summary, if the canonical form of $1 < n = p_1^{\alpha_1} \dots p_r^{\alpha_r}$, then

$$\varphi(n) = n \prod_{i=1}^r \left(1 - \frac{1}{p_i}\right).$$

Theorem 8 (Euler-Fermat). *If $1 < n \in \mathbb{Z}$ and $\gcd(a, n) = 1$ for $a \in \mathbb{Z}$, then $a^{\varphi(n)} \equiv 1 \pmod{n}$.*

3 Probabilistic primality testing

If p is a prime number, then for any $1 < a < n - 1$, due to Euler-Fermat Theorem $a^{p-1} \equiv 1 \pmod{p}$. This statement is known as *Fermat's little theorem* and we can use it as primality testing for $n > 2$ odd integer:

1. Select randomly $a \in_R \{2, \dots, n - 2\}$.
2. If $\gcd(a, n) = 1$ and $a^{n-1} \equiv 1 \pmod{n}$, then n is probably a prime number. Otherwise it is composite.

There are examples of such composite numbers n that for every base a , where $\gcd(a, n) = 1$ the property $a^{n-1} \equiv 1 \pmod{n}$ still holds. These are called *Carmichael numbers* and there are infinitely many of them.

We can use additional properties for further testing.

Theorem 9. *A positive integer p is a prime number if and only if the only solutions of $x^2 \equiv 1 \pmod{p}$ are $x \equiv \pm 1 \pmod{p}$. On the residue system level this means that p is a prime number if and only if in \mathbb{Z}_p the square roots of 1 are 1 and $p - 1$.*

Let $n - 1 = 2^s q$, where q is odd. Combining Fermat's little theorem and the previous property of prime numbers, the sequence

$$a^{2^s q} \pmod{n}, a^{2^{s-1} q} \pmod{n}, \dots, a^q \pmod{n}$$

Algorithm 8 Miller-Rabin probabilistic primality test

```
1: procedure MILLERRABIN( $n$ )
2:   Compute integers  $s, q$  such that  $n - 1 = 2^s q$  and  $q$  is odd.
3:   Select  $a \in_R \{2, \dots, n - 2\}$ .
4:    $x \leftarrow a^q \bmod n$ 
5:   if  $x = 1$  then
6:     return probably prime
7:   end if
8:   for  $k = 0, \dots, s - 1$  do
9:     if  $x = n - 1$  then
10:      return probably prime
11:    end if
12:     $x \leftarrow x^2 \bmod n$ .
13:  end for
14:  return composite
15: end procedure
```

must start with at least one 1 and if there are any elements not equal to 1, the first such element must be $n - 1$.

Based on these arguments we arrive the Miller-Rabin primality testing algorithm.

The probability of false positive response $p < \frac{1}{4}$. If we repeat the trial k times independently, then $p < \frac{1}{4^k}$.
